

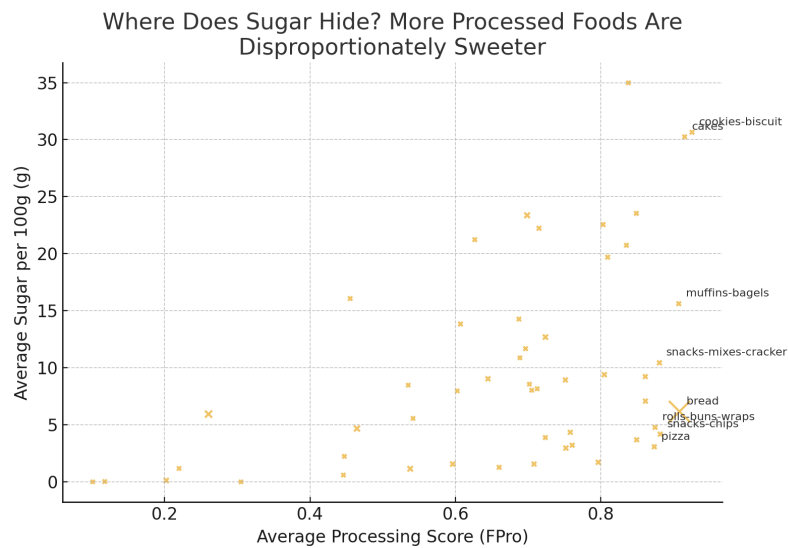

Figure 1:

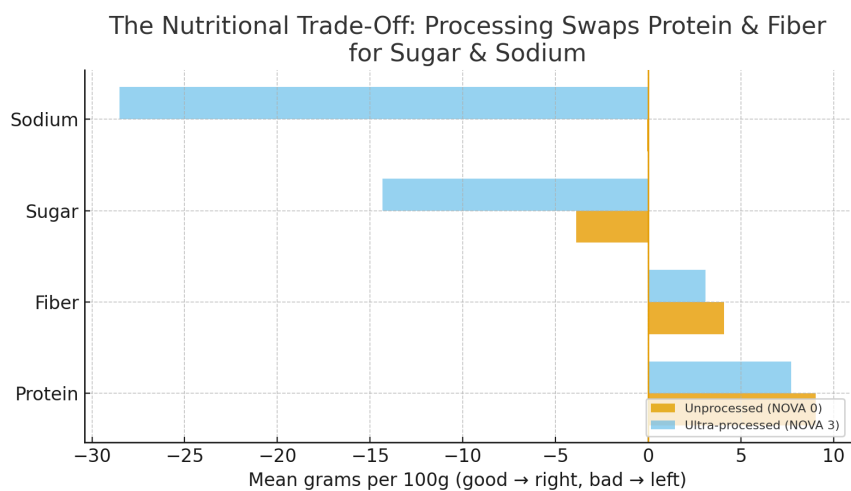

Figure 2:

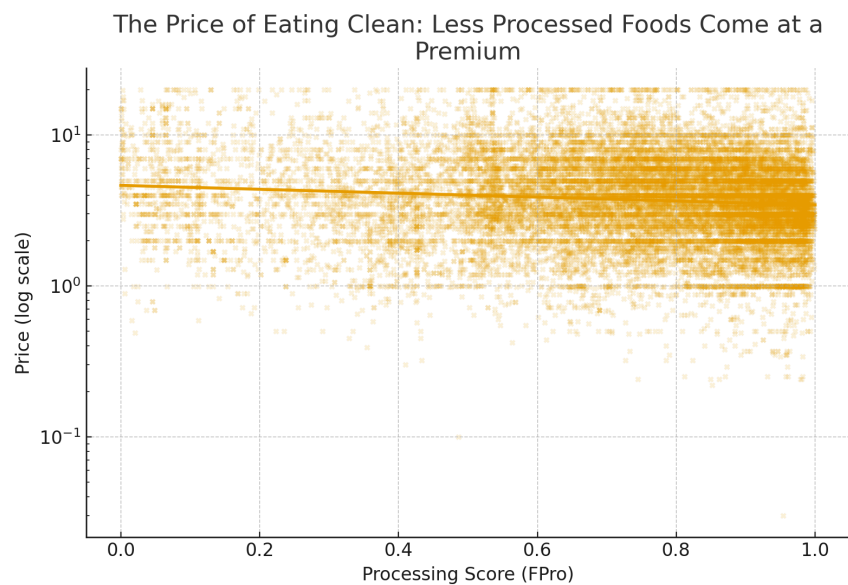

Figure 3:

Which plot I prefer and why:

Out of the three visualizations, I prefer figure 2 which displays the data for the nutritional tradeoffs of swapping taste for nutrition. I thought of doing a visualization of this because I recently read an article about how processed food is manufactured in a way that is meant to stimulate tastebuds to become addicted and hinders one's hormones that signals for fullness. I found it really interesting that there is so much science and intention behind processed foods and was curious on how these intentions affect the nutritional aspect. Figure 2 was the most effective for my curiosity of just how much sugar and sodium are swapped with more beneficial nutrients like protein and fiber. It transforms nutritional data into a visual balance sheet like visualization to communicate the trade offs of food processing by positioning beneficial nutrients (protein and fiber) to the right and harmful ones (sugar and sodium) to the left. The chart visually displays the moral and dietary harms of processed foods.
